

# Python

## Sets

Thanks to all contributors:

Ag Stephens, Alan Iwi and Tommy Godfrey.

# Sets in Python

- A type of collection (as are lists and tuples).
- Main differences from a list:
  - Unordered collection:
    - not indexed by number
    - printing / looping over set gives elements in no particular order
- Collection of distinct items:
  - The same element can only appear once.
- Analogous to sets in mathematics.

# Why use sets? An example.

- Suppose we have meteorological data at various measurement sites.
- We want to ask questions such as:
  - which sites have both wind **and** temperature data?
  - which sites have either wind **or** temperature data?
- We can store information in sets, e.g.:
  - the set of sites that have wind data
  - the set of sites that have temperature data
- Answer these questions intuitively and efficiently using Python set operations like **intersection** or **union**.

# How to construct sets in python

- Using `{ . . . }` from specified items, e.g.: `{2, 3, 4}`
- Using `set(...)` from anything you can loop over, e.g.
  - `set([0, 1, 2, 3])`
  - `set('fred')`    *← loop over characters*
  - but not: ~~`set(0, 1, 2, 3)`~~    *← needs 1 thing to loop over*
- For an empty set, use: `set()`
  - because `{ }` means something else

# Sets are mutable

```
>>> a = {10, 11, 12}
```

```
>>> a.add(13)
```

```
>>> a.remove(11)
```

```
>>> print(a)
```

```
set([10, 12, 13])      ← NB not ordered
```

```
>>> a.clear()    ← remove all items
```

# Find unique items in a collection

```
letters = set()
for char in 'ichthyosaur':
    letters.add(char)
print(letters)
```

```
set(['a', 'c', 'i', 'h', 'o', 's', 'r', 'u', 't', 'y'])
```

Note 'h' only appears once, and no particular order

- or simply:

```
letters = set('ichthyosaur')
```

# Set operations

- `len(a)` gives the number of elements
- Many operations on two sets exist
  - comparisons
  - combinations
  - many ***operators*** have equivalent ***methods***
  - see following slides

# Set comparisons

- return True or False

`a <= b`      `a.issubset(b)`

`a >= b`      `a.issuperset(b)`

`a < b`      ***strict subset***

`a > b`      ***strict superset***

`a == b`      ***identical***

# Set combinators

- returning a new set

```
a = { 2, 3 }
```

```
b = { 3, 4 }
```

<code>a   b</code>	<code>a.union(b)</code>	<code>{2, 3, 4}</code>
<code>a &amp; b</code>	<code>a.intersection(b)</code>	<code>{3}</code>
<code>a - b</code>	<code>a.difference(b)</code>	<code>{2}</code>
<code>a ^ b</code>	<code>a.symmetric_difference(b)</code>	<code>{2, 4}</code>

# Set operators vs methods

- operators act on two sets
- the equivalent methods act on anything you can loop over

```
set1 = { 2, 3 }
```

```
set2 = { 3, 4 }
```

```
print(set1 - set2)
```

```
{2}
```

```
tup = ( 3, 4 )
```

```
print(set1 - tup)
```

```
TypeError
```

```
print(set1.difference(tup))
```

```
{2}
```
